

## Named Slots

- By giving each slot a *name*, we can have multiple slots within a single component (i.e., multiple places where the parent can provide custom HTML).
- If we do not give a `<slot>` a name, Vue will assign it the name **default**. You can only use one `<slot>` without a name.

## Multiple Slots in the Parent

- The parent component uses the **<template v-slot:slotName >** syntax to target a specific slot by name.
- We can also use the shortcut **<template #slotName>**. ESLint and the Vue Style Guide prefer this approach.

## Testing Named Slots

- When testing with Vue Testing Library, provide the **slots** property in the configuration object.
- The object's properties will be the slot names and its values are strings with the HTML content to place into that slot.
